Introduction to Security in a Cloud-Enabled World

Cloud security is a partnership

The security of your Microsoft cloud services is a partnership between you and Microsoft.

Microsoft

You

Microsoft cloud services are built on a foundation of trust and security. Microsoft provides you security controls and capabilities to help you protect your data and applications. You own your data and identities and the responsibility for protecting them, the security of your on-premises resources, and the security of cloud components you control (varies by service type).

Microsoft’s trustworthy cloud

<table>
<thead>
<tr>
<th>Cybersecurity</th>
<th>Best-in-class security with decades of experience building enterprise software and online services.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data Privacy</td>
<td>Privacy by design with a commitment to use customers’ information only to deliver services and not for advertisements.</td>
</tr>
<tr>
<td>Compliance</td>
<td>Commitment to industry standards and organizational compliance.</td>
</tr>
<tr>
<td>Transparency</td>
<td>Visibility into how your data is handled and used, operational practices, Law Enforcement Reports, and Transparency Centers.</td>
</tr>
</tbody>
</table>

The responsibilities and controls for the security of applications and networks vary by the service type.

SaaS
Software as a Service

Microsoft operates and secures the infrastructure, host operating system, and application layers. Data is secured at datacenters and in transit between Microsoft and the customer. You control and secure your data and identities, including configuring the set of application controls available in the cloud service.

Azure PaaS
Platform as a Service

Microsoft operates and secures the infrastructure and host operating system layers. You control and secure your data, identities, and applications, including applying any infrastructure controls available from the cloud service. You control all application code and configuration, including sample code provided by Microsoft or other sources.

Azure IaaS
Infrastructure as a Service

Microsoft operates and secures the base infrastructure and host operating system layers. You control and secure data, identities, applications, virtualized operating systems, and any infrastructure controls available from the cloud service.

Private cloud

Private clouds are on-premises solutions that are owned, operated, and secured by you. Private clouds differ from traditional on-premises infrastructure in that they follow cloud principles to provide cloud availability and flexibility.

Keys to success

Enterprise organizations benefit from taking a methodical approach to cloud security. This involves investing in core capabilities within the organization that lead to secure environments.

Governance & Security Policy

Microsoft recommends developing policies for how to evaluate, adopt, and use cloud services to minimize creation of inconsistencies and vulnerabilities that attackers can exploit.

Ensure governance and security policies are updated for cloud services and implemented across the organization:

- Identity policies
- Data policies
- Compliance policies and documentation

Administrative Privilege Management

Your IT administrators have control over the cloud services and identity management services, making them a dependency for cloud security. The privileged accounts, credentials, and workstations where the accounts are used must be protected and monitored.

Identity Systems and Identity Management

Identity services provide the foundation of security systems. Most enterprise organizations use existing identities for cloud services and these identity systems need to be secured at or above the level of cloud services.

- Threat Awareness

Organizations face a variety of security threats with varying motivations. Evaluate the threats that apply to your organization and put them into context by leveraging resources like threat intelligence and Information Sharing and Analysis Centers (ISACs).

Data Protection

You own your data and how it should be used, shared, updated, and published. You should classify your sensitive data and ensure it is protected and monitored wherever it is stored and while it is in transit.

Microsoft Virtual Academy

Security in a Cloud-Enabled World

Top security certifications

Many international, industry, and regional organizations independently certify that Microsoft cloud services and platforms meet rigorous security standards and are trustworthy.

By providing customers with compliant, independently verified cloud services, Microsoft also makes it easier for you to achieve compliance for your infrastructure and applications.

This page summarizes the top certifications. For a complete list of security certifications and more information, see the trust centers.

Microsoft Cloud Security for Enterprise Architects

Microsoft’s role

Microsoft is committed to the privacy and security of your data and applications in the cloud

Through industry-leading security practices and unmatched experience running some of the largest online services around the globe, Microsoft delivers enterprise cloud services customers can trust.

Microsoft has developed leading-edge best practices in the design and management of online services. This model summarizes the Microsoft comprehensive approach starting with your data and drilling down to the physical media and datacenters. Be sure to review the customer responsibilities to learn about your role in the security partnership.

Data Privacy

Data ownership

It’s your data.

We define customer data as all the data, including all text, sound, software, or image files that a customer provides, or are provided on the customers’ behalf, to Microsoft through use of the Online Services.

Data use

We do not use customer data for purposes unrelated to providing the service, such as advertising.

Disclosure of government request for data

If a government approaches us for access to customer data, we redirect the inquiry to you, the customer, whenever possible. We have and will challenge in court any invalid legal demand that prohibits disclosure of a government request for customer data.

Data encryption and rights management

Data in transit

Best-in-class encryption is used to help secure data in transit between datacenters and you, as well as at Microsoft datacenters. Additionally, customers can enable Perfect Forward Secrecy (PFS): PFS uses a different encryption key for every connection, making it more difficult for attackers to decrypt connections.

Encryption for Azure-based solutions

For Azure-based solutions, you can choose to implement additional encryption using a range of approaches — you control the encryption method and keys. Built-in TLS cryptography enables customers to encrypt communications within and between deployments, from Azure to on-premises datacenters, and from Azure to administrators and users.

Azure Key Vault

Safeguard cryptographic keys and other secrets used by cloud apps and services. Microsoft does not see or extract your keys.

Identity and access

You control access to your data and applications

Microsoft offers comprehensive identity and access management solutions for customers to use across Azure and other services such as Office 365, helping simplify the management of multiple environments and control user access across applications.

What IT architects need to know about security in Microsoft cloud services and platforms

This topic is 3 of 5 in a series

1 2 3 4 5

Data access

You are in control of your data. You have control over where your data is stored and how it is securely accessed and deleted.

Privacy reviews

As part of the development process, privacy reviews are performed to verify that privacy requirements are adequately addressed. This includes verifying the presence of privacy-related features that allow customers to control who can access their data and configure the service to meet the customer’s regulatory privacy requirements.

Data portability

It’s your data, so if you ever choose to leave the service, you can take your data with you.

Data at rest

Office 365 and other SaaS services use encryption at rest to protect your data on Microsoft servers.

Azure Rights Management (Azure RMS)

Azure RMS uses encryption, identity, and authorization policies to help secure your files and email. Protection stays with the files and emails, independently of the location — inside or outside your organization, networks, file servers, and applications.

- You can use Azure RMS with Office 365: SharePoint Online and Exchange Online.
- You can configure Azure RMS for your entire organization.
- You can bring your own key to comply with your organization policies.

Identity and access monitoring offer enhanced security.

Third-party SaaS identity management

Azure AD enables easy integration and single sign-on to many of today’s popular SaaS applications, such as Salesforce.

Protecting Data and Privacy in the Cloud

Read more...

Azure Rights Management

Learn more...

Azure Active Directory and Multi-Factor Authentication

Azure Active Directory enables customers to manage access to Azure, Office 365, and a world of other cloud apps. Multi-Factor Authentication and access monitoring offer enhanced security.

Third-party SaaS identity management

Azure AD enables easy integration and single sign-on to many of today’s popular SaaS applications, such as Salesforce.
Datacenter infrastructure and networking security

Operational Security for Online Services (OSA)

OSA is a framework that focuses on infrastructure issues to help ensure secure operations throughout the lifecycle of cloud-based services.

Proactive testing and monitoring

Microsoft Digital Crimes Unit

The Microsoft Digital Crimes Unit (DCU) is a unique team in the technical industry, focused on making the Internet safe by disrupting some of the most difficult cybercrime threats facing society today.

Physical datacenter security

24-hour monitored physical security

Datacenters are physically constructed, managed, and monitored to shelter data and services from unauthorized access as well as environmental threats.

Zero standing privileges

Access to customer data by Microsoft operations and support personnel is denied by default. When granted, access is carefully managed and logged. Datacenter access to the systems that store customer data is strictly controlled via lock box processes.

Secure development across the Microsoft cloud

Microsoft Azure, Office 365, Dynamics CRM Online, and all other business-targeted cloud services use the processes documented in the SDL.

Prevent Breach, Assume Breach

In addition to threat modeling, code reviews, and security testing (prevent breach), Microsoft takes an “assume breach” approach to protecting services and data:

- Simulate real-world breaches
- Live site penetration testing
- Centralized security logging and monitoring
- Practice security incident response

Private connection

Customers can use ExpressRoute to establish a private connection to Azure datacenters, keeping their traffic off the Internet.

Data destruction

When customers delete data or leave a service, Microsoft follows strict standards for overwriting storage resources before reuse, as well as physical destruction of decommissioned hardware. Faulty drives and hardware are demagnetized and destroyed.
Customer responsibilities and roadmap

Take a systematic approach to security for on-premises and in the cloud

While Microsoft is committed to the privacy and security of your data and applications in the cloud, customers must take an active role in the security partnership. Rising cybersecurity threats increase the requirements for security rigor and principles at all layers for both on-premises and cloud assets. Enterprise organizations are better able to manage and address concerns about security in the cloud when they take a systematic approach.

Moving workloads to the cloud shifts many security responsibilities and costs to Microsoft, freeing your security resources to focus on the critically important areas of data, identity, strategy, and governance.

Important: How to use this page

This page includes a methodical list of actions that Microsoft recommends to defend your data, identities, and applications against cybersecurity threats. These actions are categorized and presented in a stack. Categories at the top of the stack apply across SaaS, PaaS, IaaS, and private cloud. The scope of categories decreases further down the stack.

SaaS
Software as a Service

Azure PaaS
Platform as a Service

Azure IaaS
Infrastructure as a Service

Private cloud

1. Security strategy, governance, and operationalization: Provide clear vision, standards, and guidance for your organization

A. Develop cloud security policies

Policies enable you to align your security controls with your organization’s goals, risks, and culture. Policies should provide clear, unequivocal guidance to enable good decisions by all practitioners.

- **Document security policies** in enough detail to guide personnel into quick and accurate decisions while adopting and managing cloud services. Ensure you have sufficient detail on policy areas that are well-established and critically important to your security posture.
- **Balance security and usability.** Security controls that overly restrict the ability of admins and users to accomplish tasks will be worked around. Build buy-in through both threat education and inclusion in the security design process.
- **Document protocols and processes** for performing critically important security tasks such as using administrative credentials, responding to common security events, and recovering from significant security incidents.
- **Embrace "Shadow IT."** Identify the unmanaged use of devices, cloud services, and applications. Identify business requirements that led to their use as well as the business risk that they bring. Work with business groups to enable required capabilities while mitigating risks.

B. Manage continuous threats

The rate of threats and changes in security requires operational capabilities and constant adjustments. Proactively manage this risk:

- **Establish operational capabilities** to monitor alerts, investigate incidents, initiate remediation actions, and integrate lessons learned.
- **Build external context** of threats using available resources such as threat intelligence feeds, Information Sharing and Analysis Centers (ISACs), and other means.
- **Validate your security posture** by authorized red team and/or penetration testing activity. (White paper: Microsoft Enterprise Cloud Red Team)
- **Define a monthly cadence** to review and integrate updates of cloud capabilities, regulatory and compliance requirements, evolving threats, and organizational objectives.
- **Prevent configuration drift with periodic reviews** to ensure technologies, configurations, and operational practices stay in compliance with your policies and protocols.

C. Manage continuous innovation

The rate of capability releases and updates from cloud services requires proactive management of potential security impacts:

- **Identify your most critical assets** such as mission-critical data, applications, and dependencies. Security for these must be at a higher level without compromising usability.
- **Enhancing isolation between security zones** by increasing rigor of exception management. Apply threat modeling techniques to all authorized exceptions and analysis of these application data flows including identities used, data transmitted, and platform trustworthiness, and ability to inspect interaction.
- **Focus containment within a security zone** on preserving integrity of the administrative model rather than on network isolation.
2. Administrative control: Defend against the loss of control of your cloud services and on-premises systems

A. Least privilege admin model
Continue on the journey towards least privilege of your administrative control by applying approaches including:
- Limit the number of administrators or members of privileged groups.
- Delegate less privileges to accounts.
- Provide privileges on demand.
- Have existing administrators perform tasks instead of adding additional administrators.
- Provide processes for emergency access and rare use scenarios.

SaaS
Software as a Service

B. Harden security dependencies
Security dependencies are anything that has administrative control of an asset. Ensure that you harden all dependencies at or above the security level of the assets they control. Security dependencies for cloud services commonly include identity systems, on-premises management tools, administrative groups and accounts, and workstations where these accounts logon.

B2C

C. Use strong authentication
Use credentials secured by hardware or Multi-Factor Authentication (MFA) for all identities with administrative privileges. This mitigates risk of stolen credentials being used to abuse privileged accounts.

Azure Multi-Factor Authentication
Microsoft Passport and Windows Hello

C2B

D. Use dedicated admin accounts and workstations
Separate high impact assets from highly prevalent Internet browsing and email risks:
- Use dedicated accounts for privileged administrative roles for cloud services and on-premises dependencies.
- Use dedicated, hardened workstations for administration of high-business impact IT assets.
- Do not use high privilege accounts on devices where email and web browsing take place.

White paper: Security Management in Microsoft Azure
Resource center: Mitigating pass-the-hash and other credential theft

D2C

E. Enforce Stringent Security Standards
Administrators control significant amounts of organizational assets. Rigorously measure and enforce stringent security standards on administrative accounts and systems. This includes cloud services and on-premises dependencies such as Active Directory, identity systems, management tools, security tools, administrative workstations, and associated operating systems.

F. Monitor admin accounts
Closely monitor the use and activities of administrative accounts. Configure alerts for activities that are high impact as well as for unusual or rare activities.

White paper: Microsoft Azure Security and Audit Log Management
Auditing in Office 365

G. Educate and empower admins
Educate administrative personnel on likely threats and their critical role in protecting their credentials and key business data. Administrators are the gatekeepers of access to many of your critical assets. Empowering them with this knowledge will enable them to be better stewards of your assets and security posture.

3. Data: Identify and protect your most important information assets

A. Establish information protection priorities
The first step of protecting information is identifying what to protect. Develop clear, simple, and well-communicated guidelines to identify, protect, and monitor the most important data assets anywhere they reside.

Resource center: Data governance
Data classification toolkit

A2C

B. Protect High Value Assets (HVA)
Establish the strongest protection for assets that have a disproportionate impact on the organization’s mission or profitability. Perform stringent analysis of HVA lifecycle and security dependencies, establish appropriate security controls and conditions.

B2C

C. Find and protect sensitive assets
Identify and classify sensitive assets. Define the technologies and processes to automatically apply security controls.

Data classification toolkit
Encryption in Office 365
Active Directory Rights Management Service
Azure Rights Management
Data loss prevention in Office 365
Blog: O365 Data Loss Prevention (DLP)
Office 365 Reports
Document fingerprinting
Azure Key Vault

C2B

D. Set organizational minimum standards
Establish minimum standards for devices and accounts accessing any data assets belonging to the organization. This can include device configuration compliance, device wipe, enterprise data protection capabilities, user authentication strength, and user identity.

Windows 10 Enterprise Data Protection
Manage access to email and services with conditional access for Microsoft Intune

D2C

E. Establish user policy and education
Users play a critical role in information security and should be educated on your policies and norms for security aspects of data creation, classification, compliance, sharing, protection, and monitoring.

4. User identity and device security: Strengthen protection of accounts and devices

A. Use Strong Authentication
Use credentials secured by hardware or Multi-Factor Authentication (MFA) for all identities to mitigate the risk that stolen credentials can be used to abuse accounts:
- User identities hosted in Azure Active Directory (Azure AD).
- On-premises accounts whose authentication is federated from on-premises Active Directory.

A2C

B. Manage trusted and compliant devices
Establish, measure, and enforce modern security standards on devices that are used to access corporate data and assets. Apply configuration standards and rapidly install security updates to lower the risk of compromised devices being used to access or tamper with data.

Manage device compliance policies for Microsoft Intune
Microsoft Security Compliance Manager (SCM)
Enhanced Mitigation Experience Toolkit (EMET)

C2B

C. Educate, empower, and enlist users
Users control their own accounts and are on the front line of protecting many of your critical assets. Empower users to be good stewards. At the same time acknowledging that user activities and errors can contribute to security risk that can be mitigated but never completely eliminated. Focus on measuring and reducing risk from users:
- Educate users on likely threats and their role in protecting business data.
- Increase adversary cost to compromise user accounts.
- Explore gamification and other means of increasing user engagement.

C2B

D. Monitor for account and credential abuse
One of the most reliable ways to detect abuse of privileges, accounts, or data is to detect unusual or rare activities of an account.
- Identify activity that is normal and physically possible. Alert on unusual activity to enable rapid investigation and response.
- For accounts in Azure AD, use the integrated analytics to detect unusual activity.

White paper: Microsoft Azure Security and Audit Log Management
Auditing in Office 365

D2C

Continued on next page
5. Application security: Ensure application code is resilient to attacks

A. Secure applications that you acquire
- Review the security development processes and operational practices of vendors before acquiring applications. Build this into your acquisition process.
- Follow security configuration guidance and recommendations provided by the vendor for the application.
- Apply all vendor security updates as rapidly as your testing requirements allow. Ensure to update middleware and dependencies installed with the applications.
- Discontinue your use of software before it reaches end of support status.

B. Follow the Security Development Lifecycle (SDL)
Software applications with source code you develop or control are a potential attack surface. These include PaaS apps, PaaS apps built from sample code in Azure like WordPress sites, and apps that interface with Office 365. Follow code security best practices in the Microsoft Security Development Lifecycle (SDL) to minimize vulnerabilities and their security impact.
See: [www.microsoft.com/sdl](http://www.microsoft.com/sdl)

6. Network: Ensure connectivity, isolation, and visibility into anomalous behavior

A. Update your network security strategy and architecture for cloud computing
Ensure your network architecture is ready for the cloud by updating your current approach or taking the opportunity to start fresh with a modern strategy for cloud services and platforms. Align your network strategy with your:
- Overall security strategy and governance
- Containment model and identity strategy
- Cloud services capabilities and constraints
Your design should address securing communications:
- Inbound from the Internet
- Between VMs in a subscription
- Across subscriptions
- To and from on-premises networks
- From remote administration hosts

B. Optimize with cloud capabilities
Cloud computing offers uniquely flexible network capabilities as topologies are defined in software. Evaluate the use of these modern cloud capabilities to enhance your network security auditability, discoverability, and operational flexibility.

C. Manage and monitor network security
Ensure your processes and technology capabilities are able to distinguish anomalies and variances in configurations and network traffic flow patterns. Cloud computing utilizes public networks, allowing rapid exploitation of misconfigurations that should be avoided or rapidly detected and corrected.
- Closely monitor and alert on exceptions.
- Apply automated means of ensuring networking configuration stays correct and unusual traffic patterns are detected.

White paper: Microsoft Azure Network Security

7. Operating system and middleware: Protect integrity of hosts

A. Virtual operating system
Secure the virtual host operating system (OS) and middleware running on virtual machines. Ensure that all aspects of the OS and middleware meet or exceed the level required for the host including:
- Administrative privileges and practices
- Software updates for OS and middleware
- Security Configuration Baseline
- Use of Group Policy Objects (GPOs)
- Installation methods and media
- Use of scheduled tasks
- Anti-malware and intrusion detection/prevention
- Host firewall and IPsec configurations
- Event log configuration and monitoring

B. Virtual OS management tools
System management tools have full technical control of the host operating systems including the applications, data, and identities (making these a security dependency of the cloud service). Secure these tools at or above the level of the systems they manage. These tools typically include:
- Configuration Management
- Operations Management and Monitoring
- Backup
- Security Update and Patch Management
8. Private cloud or on-premises environments: Secure the foundation

A. Physical network
Secure the networks you install and operate in your datacenters. Follow the guidelines and principles outlined in the Operating system and middleware section (above).

B. Fabric and datacenter identities
The accounts used to manage the fabric have technical control of the fabric, making them a security dependency of the fabric and all the services hosted on it. These include local and domain accounts with administrative privileges over systems including:
- Active Directory domains where fabric resources are joined
- Virtualization host operating systems
- Fabric management tools
Follow the security guidelines in the Administrative privileges and identities section (above) for these resources.

C. Server and device firmware
Firmware is the software embedded into the fabric hardware and is a security dependency of the cloud services and a potential attack vector. Validate and harden this software to the best of your ability, including the following:
- Baseboard Management Controllers (BMCs) for hardware "lights out" or remote access
- Server motherboard firmware
- Interface card firmware
- Dedicated appliance firmware/software

D. Storage
The security assurances of on-premises services depend on the security of the storage systems. These include:
- Storage management tools
- Storage administrator accounts and groups
- Workstations used by storage administrators
- Storage device operating systems and firmware
Secure these systems at or above the level required for all applications, identities, operating systems, and data hosted on them.

E. Physical operating systems and middleware
Operating systems and middleware installed on physical server hardware are a security dependency of the services that run on them. Secure these resources at or above the level required for the services and data hosted on the fabric using the guidelines in the Operating system and middleware section (above).

F. Physical security
Physical security assurances of the hardware hosting a cloud service must be at or above the level required for all of the applications, data, and identities hosted on it. Physical security protects all of the security dependencies, including the following:
- Server hardware
- Storage devices
- Network devices
- Administrative workstations
- Installation media
- Smart cards, one-time password tokens, and any passwords written on paper

G. Fabric management
The security assurances of the fabric are dependent on the security integrity of the software and tools used to manage it. These can include:
- Configuration management
- Operations management
- Virtual machine management
- Backup
Secure these resources at or above the level required for the services and data hosted on the fabric.

H. Virtualization solution
Virtual machines depend on the virtualization fabric for security assurances. The fabric includes:
- Virtualization management tools
- Virtualization administrators
- Workstations used by these administrators
- VM host operating systems
- Firmware on the VM host hardware
Secure these systems at or above the level required for all applications, identities, and data hosted on the virtualization solution.

For information about how Azure datacenters are secured, see:
- Trusted Cloud: Microsoft Azure Security, Privacy, and Compliance
- Operational Security for Online Services Overview
A Cloud Security Journey

Microsoft has experience and expertise helping customers move workloads to the cloud:
- Securing cloud services for our customers.
- Helping our customers move their workloads to cloud services with our professional services.
- Optimizing security protocols by hosting our corporate IT workloads on Microsoft public cloud services.

Microsoft has extensive experience with cybersecurity threats and provides professional services to our customers to assist with:
- Attack detection and prevention
- Incident response
- Recovery from attacks

This page lays out a typical cloud security roadmap based on our experience realizing business value from the cloud and defending cloud-based assets against cybersecurity threats.

A typical journey to the cloud includes key security transformations that span your organization’s IT culture, governance, policy, processes, technology, and security controls. The most common changes and challenges are:
- Establishing and validating trust of cloud providers.
- Shifting primary defenses to identity, data, and application layers.
- Keeping up with cloud security capabilities and controls.
- Keeping up with cybersecurity threats.

How can Microsoft Services help you?

Assessing and planning cloud security
Building a complete roadmap for cloud security requires knowing where you stand. Microsoft can help you build a tailored roadmap for:
- Security strategy and capabilities.
- Identity strategy and alignment.
- Office 365 security.
- Azure subscription and workload security.
- High-value asset discovery and protection.
- Information protection and rights management.

Threat detection and incident response
Microsoft has world-class incident response teams with extensive experience handling targeted attacks by determined adversaries. Microsoft can help you with detecting these threats, hunting for adversaries in your environment, responding to incidents, and recovering IT service integrity and availability after an attack:
- Threat detection as a managed security service.
- Incident response support (over the phone and onsite).
- Proactive hunt for persistent adversaries in your environment.
- Recovery from cybersecurity attacks.

Cloud workload migration and hardening
Microsoft can help you harden your current cloud assets, securely migrating workloads to the cloud, and creating new workloads in the cloud that are hardened from day one. Microsoft has expertise and experience to help you maximize your security assurances of cloud infrastructure and brand presence assets:
- Office 365 security configuration hardening.
- Azure workload analysis, migration, and security hardening.
- Hardened workstations for social media and brand management.
- Hardened consoles for cloud infrastructure administration.
- Hardening applications and application development processes for PaaS and hybrid applications using the Microsoft Security Development Lifecycle (SDL) and international standard ISO 27034-1.
- Designing, implementing, and securing private clouds.

Support, operations, and service management: sustaining the gains
Security is a journey and sustaining your security assurances requires ongoing investment into a maintainable operations model that encompasses people, processes, and technology. Microsoft Services provides a wide range of cloud and security IT support services, including IT staff training, health and risk assessments, and assistance with adoption of recommended practices. Microsoft IT Service Management (ITSM) services empower you to implement lifecycle management within IT by addressing the people and processes readiness required to fully leverage technology capabilities effectively.

Administration, identity, and host security
Securing administrative privileges is critical for cloud services and the on-premises identity and security capabilities they depend on. Microsoft has developed industry leading solutions to protect and monitor administrative privileges that address challenges with people, process, and technology elements:
- Hardening administration of cloud services.
- Hardening administration of Active Directory and identity systems.
- Hardening infrastructure management tools and systems.
- Just-in-time and just enough administrative privileges.

Where to start?
Microsoft recommends starting with a view of your entire organization and addressing your top risks first:
- Assess your cloud security posture to get a broad view of the road ahead.
- Enable advanced threat detection.
- Address top risks — Protect business-critical social accounts and cloud administrative privileges accounts with hardened workstations and security tailored to those roles.

Getting started

Engaging Microsoft professional services
If you would like assistance with any of the cybersecurity or cloud security capabilities described on this page, contact your Microsoft Services representative, or visit www.microsoft.com/services.

Security incident response
Customers with a Premier Support Agreement have ready access to highly specialized security support engineers and onsite incident response teams. For customers with an existing Premier agreement, no additional contracting action is necessary to initiate incident response activities from Microsoft. Contact your technical account manager (TAM) for more information.
